Foot and Mouth Disease

Foot and Mouth Disease (FMD) is a highly contagious viral disease of cattle and swine, as well as sheep, goats, deer, and other cloven-hoofed ruminants. The US has been free of FMD since 1929. Although rarely transmissible to humans, FMD is devastating to livestock and has critical economic consequences with potentially severe losses in the production and marketing of meat and milk.

Information on FMD is available on the Internet by visiting the Animal and Plant Health Inspection Service website at www.aphis.usda.gov/oa/fmd/index.html. This site details the causes, signs, effects, prevention, and control of FMD. This site also contains current information regarding foot-and-mouth disease and traveler questions.

Immediately report signs of a possible foreign animal disease to the USDA Area Veterinarian in Charge (AVIC), Dr. David Vogt at 410-349-9708 during the hours of 8 AM to 5 PM, or 410-279-3037 (cell). The Maryland State Veterinarian, Dr. Roger Olson, Maryland Department of Agriculture, 410-841-5810, has developed a response plan should FMD be introduced in the State.

The United States remains free of any cases of Bovine Spongiform Encephalopathy and Foot and Mouth Disease.

Report signs of any suspicious cases to the USDA Area Veterinarian in Charge at 410-349-9708.

West Nile Virus Update

On May 1, 2001 following US Centers for Disease Control and Prevention guidelines, Maryland launched a comprehensive surveillance plan for the detection of West Nile virus (WNV). This response was initiated following the first appearance of West Nile virus in the Western Hemisphere in 1999 and the predicted geographic spread of the disease.

To reduce the threat of West Nile virus infection in human and equine populations, the Maryland Arbovirus Surveillance and Management Plan, 2001 highlighted four critical areas of surveillance that included the detection of virus in mosquito, bird, horse, and human populations. By conducting surveillance activities such as mosquito trapping and testing for West Nile virus, and by examining any horse suspected of dying from encephalitis or meningitis, state officials were able to determine when West Nile virus moved into a geographic area and issue appropriate prevention guidelines.

In 1999, Maryland's only West Nile virus-positive finding was a single dead crow found in downtown Baltimore; in 2000, 50 positive birds were found throughout the state. As of 12/31/01 the Maryland Department of Health and Mental Hygiene (DHMH), Laboratories Administration, confirmed 454 dead birds, 18 mosquito pools, 7 horses and 6 humans that have tested positive for WNV. Three fatalities occurred, 2 humans and 1 equine case. Due to cooling temperatures and subsequent decreased mosquito populations, active avian WNV surveillance ceased on November 1, 2001 but equine and small animal surveillance continues.

The upcoming WNV season will begin on May 1, 2002. Details will be provided soon.
It has come to the attention of the Center for Veterinary Public Health (CVPH) that many practitioners are administering a 3-year rabies vaccine to either a dog or cat and stating that it is protective for only 1 year because the animal is a few months overdue in receiving its booster dose. The first (primary) rabies vaccine administered to a dog or cat is protective for only 1 year. Although it is recommended that the first rabies vaccination be administered to the animal at 4 months of age, if the animal is older (at the time of its primary rabies vaccination), the immunization is still protective for only one year.

If a triennial vaccine is used for the subsequent doses (following the primary dose) then each vaccination is protective for 3 years regardless of whether a time gap occurred between when the rabies booster dose was due and when it was actually administered! [Of course, if you are administering a 1-year vaccine then the duration of protection is only 1 year for every vaccination.]

The CVPH follows the recommendations of the National Association of State Public Health Veterinarians (NASPHV) that state “If a previously vaccinated animal (dog or cat) is overdue for a booster, it should be revaccinated with a single dose of vaccine. Immediately following the booster, the animal is considered currently vaccinated and should be placed on an annual or triennial schedule depending on the type of vaccine used.”

Please be aware that this practice is only recognized for those overdue dogs and cats requiring a routine booster dose of rabies vaccine. It is not applicable to overdue animals facing a quarantine or isolation procedure following an exposure to a potentially rabid animal. If you have any questions, please call our office. If you would like a copy of the 2001 NASPHV Compendium to Control Rabies, please contact our office or visit the American Veterinary Medical Association (AVMA) website at www.avma.org/pubhlth/rabcont.asp. The 2002 Compendium will be available later this year.

An important safety tip for small animal as well as large animal practitioners:

Please consider using standard precautions (latex gloves at a minimum) for yourself and especially your staff when examining a stray, feral, or unfamiliar patient, or a patient exhibiting neurological signs to prevent non-bite exposures to potentially rabid animals. Many rabies post-exposure prophylaxis (PEP) treatments have been administered to veterinarians and veterinary staff members because of direct skin contact with rabies virus-laden saliva. Although gloves will probably not protect one against a bite exposure to a rabid animal, many more PEP treatments are administered for non-bite exposures than true bite exposures. Try to be proactive instead of reactive regarding you and your staff’s personal safety to minimize your risk of rabies exposures.

In the United States in 2000, 5 human fatalities due to rabies occurred in California, Georgia, Minnesota, New York and Wisconsin. Four cases were due to bat-strain variants (Mexican free-tailed, Silver-haired or Eastern pipistrelle) and 1 case was an African-canine variant. The canine-variant case was imported! [Of course, if you are administering a 1-year vaccine then the duration of protection is only 1 year for every vaccination.]

2000 Human Rabies Update

During the past decade in Maryland, cats have been the fourth most prevalent species positive for rabies following raccoons, skunks, and foxes. But cats are the most prevalent domestic species with confirmed rabies. Please ensure that all cats are properly immunized against rabies according to Maryland regulations.

For a copy of a detailed report on laboratory-confirmed rabid animals in Maryland in 2000, please contact our office at 410-767-6703 or access it on the web at www.edcp.org/html/vet_med.html.

For the complete text articles about the human rabies fatalities, please contact our office or see the following Morbidity and Mortality Weekly Report websites:

www.cdc.gov/mmwr/preview/mmwrhtml/mm4949a3.htm (US cases)

www.cdc.gov/mmwr/preview/mmwrhtml/mm4949a4.htm (Canada case).

For a brochure that addresses bats and rabies:

**Bovine Spongiform Encephalopathy**

Bovine spongiform encephalopathy (BSE, or "mad cow disease") and a disease in humans called variant Creutzfeldt-Jakob disease (vCJD) have a causal relationship. Both disorders are invariably fatal brain diseases with unusually long incubation periods (measured in years), and are caused by an unconventional transmissible agent. Current scientific research indicates that prions are the transmissible pathogenic agents responsible for diseases such as BSE, vCJD, and scrapie. There have been no documented human cases of vCJD nor of BSE in cattle in the US. Variant CJD is not the same disease as conventional CJD. CJD has a worldwide distribution (including the US) and an overall incidence rate of 1 human case per 1 million people annually.

Public health control measures to prevent BSE-infected tissues from entering animal and human food supplies include BSE surveillance, sick animal culls, or the ban of specified risk materials. Cow's milk and milk products are not believed to pose any risk for transmitting the BSE agent. Although BSE has not been detected in cattle in the United States, according to the Animal and Plant Health Inspection Service of the US Department of Agriculture (USDA, APHIS), active BSE surveillance is ongoing. To maintain our BSE-free status the USDA is testing cow tissues from at least 100,000 random animals annually for the BSE agent. The USDA is testing for BSE in cattle born in 1997 or later.

A new federal disease control program designed to accelerate the eradication of the fatal brain disease, scrapie, from the nation's sheep flocks and goat herds began on November 19, 2001. The program requires that ear tags are to be placed in all sheep over 18 months of age and some types of goats by their owners before they are sold or transported to a sale, show, or exhibition. Flocks enrolled in the Scrapie Flock Certification Program will not need to make any changes. For additional information and to obtain the required USDA tags, please contact your local USDA, APHIS office at 1-866-873-2824 (1-866-USDA-TAG).

---

**Small Ruminant Practitioners**

A new federal disease control program designed to accelerate the eradication of the fatal brain disease, scrapie, from the nation’s sheep flocks and goat herds began on November 19, 2001. The program requires that ear tags are to be placed in all sheep over 18 months of age and some types of goats by their owners before they are sold or transported to a sale, show, or exhibition. Flocks enrolled in the Scrapie Flock Certification Program will not need to make any changes. For additional information and to obtain the required USDA tags, please contact your local USDA, APHIS office at 1-866-873-2824 (1-866-USDA-TAG).

Dr. Jack Casper of MDA is coordinating a syndromic surveillance program to detect unusual disease occurrences within animal populations in MD. If you would like your clinic (large or small animal), kennel, zoo or research facility to be included in this important endeavor please contact Jack at:

jarucasper@comcast.net or 443-394-1449
Center for Veterinary Public Health

The Department of Health and Mental Hygiene (DHMH), Community Health Administration (CHA), Epidemiology and Disease Control Program (EDCP) includes the State Public Health Veterinarian and the Center for Veterinary Public Health (CVPH). The mission of the CVPH is the prevention and control of zoonotic and vector-borne diseases in Maryland, including rabies and Lyme disease, through surveillance, consultations, investigations, and the education of human and animal health care providers and the public. A major role of the CVPH is to provide consultations for local health departments that do not have veterinary staff. In the event of a bioterrorist act, an emerging infectious disease, or a rabies case with many questionable areas, the CVPH staff works with the local health department staff to resolve problems and find solutions. Additionally, CVPH represents the State at legislative hearings on various bills, writes regulations and fact sheets, attends meetings at the Centers for Disease Control and Prevention (CDC), writes grants, provides health education for the media, schools and the public, and coordinates with local, state, and federal agencies and medical professions. The two divisions of the CVPH (Rabies and Vector-borne Diseases and Zoonotic Diseases) coordinate with each other to produce various health-related documents, provide lectures and talks, and develop conferences and health education materials for local health departments.

Fact Sheet Information

Fact Sheets

The Department of Health and Mental Hygiene has a variety of Communicable Disease Fact Sheets available for distribution to your clients. Covering a variety of topics, these fact sheets include information about rabies, vector-borne, and other zoonotic diseases. The fact sheets may be accessed on the Internet at www.edcp.org/html/cdindex.html. You are encouraged to print out copies and freely distribute the fact sheets as needed. Included in this newsletter are the following:

- Arbovirus encephalitis
- Giardia
- Eastern equine encephalitis
- Psittacosis
- Anthrax
- Leptospirosis
- Rabies

Please contact our office with any comments regarding this newsletter or with any topics that you would like to see in the next one.

The Food and Drug Administration (FDA) has a website of one-page information fact sheets that include topics such as protecting the US from ‘mad cow disease’ and safeguarding animal health:

www.fda.gov/opacom/factsheets/justthefacts/default.htm
